STK-IN4300: lecture 3 1/ 42

STK-IN4300 - Statistical Learning Methods in Data Science

Cross-Validation: k-fold cross-validation

The cross-validation aims at estimating the expected test error,

$$\mathsf{Err} = E[L(Y, \hat{f}(X))].$$

- with enough data, we can split them in a training and test set;
- since usually it is not the case, we mimic this split by using the limited amount of data we have,
 - split data in K folds $\mathcal{F}_1,\ldots,\mathcal{F}_K$, approximatively same size;
 - use, in turn, K-1 folds to train the model (derive $\hat{f}^{-k}(X)$);
 - evaluate the model in the remaining fold,

$$CV(\hat{f}^{-k}) = \frac{1}{|\mathcal{F}_k|} \sum_{i \in \mathcal{F}_k} L(y_i, \hat{f}^{-k}(x_i))$$

estimate the expected test error as an average,

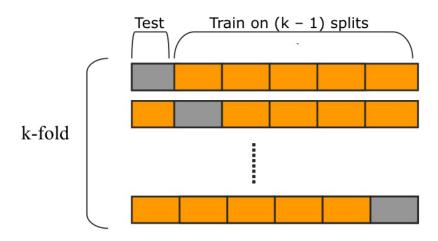

$$CV(\hat{f}) = \frac{1}{K} \sum_{k=1}^{K} \frac{1}{|\mathcal{F}_k|} \sum_{i \in \mathcal{F}_k} L(y_i, \hat{f}^{-k}(x_i)) \stackrel{|\mathcal{F}_k| = \frac{N}{K}}{=} \frac{1}{N} \sum_{i=1}^{N} L(y_i, \hat{f}^{-k}(x_i)).$$

Cross-Validation: k-fold cross-validation

(figure from http://qingkaikong.blogspot.com/2017/02/machine-learning-9-more-on-artificial.html)

STK-IN4300: lecture 3 3/42 STK-IN4300: lecture 3 4/42

Cross-Validation: choice of K

How to choose K?

- there is no a clear solution:
- bias-variance trade-off:
 - ▶ smaller the K, smaller the variance (but larger bias);
 - larger the K, smaller the bias (but larger variance);
 - extreme cases:
 - K=2, half observations for training, half for testing;
 - K = N, leave-one-out cross-validation (LOOCV);
 - LOOCV estimates the expected test error approximatively unbiased;
 - LOOCV has very large variance (the "training sets" are very similar to one another);
- usual choices are K=5 and K=10.

STK-IN4300: lecture 3 5/ 42

STK-IN4300 - Statistical Learning Methods in Data Science

Cross-Validation: further aspects

If we want to select a tuning parameter (e.g., no. of neighbours)

- train $\hat{f}^{-k}(X,\alpha)$ for each α ;
- compute $CV(\hat{f}, \alpha) = \frac{1}{K} \sum_{k=1}^{K} \frac{1}{|\mathcal{F}_k|} \sum_{i \in \mathcal{F}_k} L(y_i, \hat{f}^{-k}(x_i, \alpha));$
- obtain $\hat{\alpha} = \operatorname{argmin}_{\alpha} CV(\hat{f}, \alpha)$.

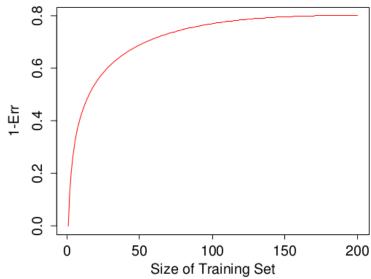

The generalized cross-validation (GCV),

$$GCV(\hat{f}) = \frac{1}{N} \sum_{i=1}^{N} \left[\frac{y_i - \hat{f}(x_i)}{1 - \operatorname{trace}(S)/N} \right]^2$$

- is a convenient approximation of LOOCV for linear fitting under square loss;
- has computational advantages.

Cross-Validation: choice of K

STK-IN4300: lecture 3 6/42

STK-IN4300 - Statistical Learning Methods in Data Science

Cross-Validation: the wrong and the right way to do cross-validation

Consider the following procedure:

- 1. find a subset of good (= most correlated with the outcome) predictors;
- 2. use the selected predictors to build a classifier;
- 3. use cross-validation to compute the prediction error.

Practical example (see R file):

- generated X, an $[N=50] \times [p=5000]$ data matrix;
- generate independently y_i , $i = 1, \ldots, 50, y_i \in \{0, 1\}$;
- the true error test is 0.50;
- implementing the procedure above. What does it happen?

STK-IN4300: lecture 3 7/ 42 STK-IN4300: lecture 3 8/ 42

Cross-Validation: the wrong and the right way to do cross-validation

Why it is not correct?

- Training and test sets are **NOT** independent!
- observations on the test sets are used twice.

Correct way to proceed:

- divide the sample in K folds;
- both perform variable selection and build the classifier using observations from K-1 folds;
 - possible choice of the tuning parameter included;
- compute the prediction error on the remaining fold.

STK-IN4300: lecture 3 9/ 42

STK-IN4300 - Statistical Learning Methods in Data Science

Bootstrap Methods: bootstrap

For example, to estimate the variance of S(Z),

$$\widehat{\mathsf{Var}}[S(Z)] = \frac{1}{B-1} \sum_{b=1}^{B} (S(Z_b^*) - \bar{S}^*)^2$$

where $\bar{S^*} = \frac{1}{B} \sum_{b=1}^B S(Z_b^*)$.

Note that:

• $\widehat{\mathsf{Var}}[S(Z)]$ is the Monte Carlo estimate of $\mathsf{Var}[S(Z)]$ under sampling from the empirical distribution \hat{F} .

Bootstrap Methods: bootstrap

IDEA: generate pseudo-samples from the empirical distribution function computed on the original sample;

- by sampling with replacement from the original dataset;
- mimic new experiments.

Suppose $Z = \{\underbrace{(x_1, y_1)}_{z_1}, \dots, \underbrace{(y_N, x_N)}_{z_N}\}$ be the training set

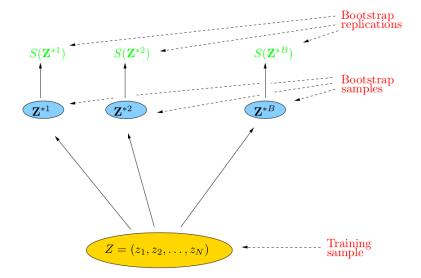

- by sampling with replacement, $Z_1^* = \{\underbrace{(y_1^*, x_1^*)}_{z_1^*}, \dots, \underbrace{(y_N^*, x_N^*)}_{z_N^*}\};$
-
- by sampling with replacement, $Z_B^* = \{\underbrace{(y_1^*, x_1^*)}_{z^*}, \dots, \underbrace{(y_N^*, x_N^*)}_{z^*_N}\};$
- use the B bootstrap samples Z_1^* , ..., Z_B^* to estimate any aspect of the distribution of a map S(Z).

STK-IN4300: lecture 3 10/ 42

STK-IN4300 - Statistical Learning Methods in Data Science

Bootstrap Methods: bootstrap

STK-IN4300: lecture 3 11/42 STK-IN4300: lecture 3 12/42

Bootstrap Methods: estimate prediction error

Very simple:

- generate B bootstrap samples Z_1^*, \ldots, Z_B^* ;
- apply the prediction rule to each bootstrap sample to derive the predictions $\hat{f}_b^*(x_i)$, $b=1,\ldots,B$;
- compute the error for each point, and take the average,

$$\widehat{\mathsf{Err}}_{\mathsf{boot}} = \frac{1}{B} \sum_{b=1}^{B} \frac{1}{N} \sum_{i=1}^{N} L(y_i, \hat{f}_b^*(x_i)).$$

Is it correct? NO!!!

Again, training and test set are **NOT** independent!

STK-IN4300: lecture 3 13/42

STK-IN4300 - Statistical Learning Methods in Data Science

Bootstrap Methods: why 0.368

 $\Pr[\text{observation } i \text{ does not belong to the boostrap sample } b] = 0.368$

Since

$$\Pr[Z_{b[j]}^* \neq y_i] = \frac{N-1}{N},$$

is true for each position [j], then

$$\Pr[Y_i \notin Z_b^*] = \left(\frac{N-1}{N}\right)^N \xrightarrow{N \to \infty} e^{-1} \approx 0.368,$$

Consequently,

 $\Pr[\text{observation } i \text{ is in the boostrap sample } b] \approx 0.632.$

Bootstrap Methods: example

Consider a classification problem:

- two classes with the same number of observations:
- predictors and class label independent \Rightarrow Err = 0.5.

Using the 1-nearest neighbour:

- if $y_i \in Z_b^* \to \hat{\mathsf{Err}} = 0$;
- if $y_i \notin Z_b^* \to \hat{\mathsf{Err}} = 0.5$;

Therefore,

$$\widehat{\mathsf{Err}}_{\mathsf{boot}} = 0 \times \Pr[Y_i \in Z_b^*] + 0.5 \times \underbrace{\Pr[Y_i \notin Z_b^*]}_{0.368} = 0.184$$

STK-IN4300: lecture 3 14/42

STK-IN4300 - Statistical Learning Methods in Data Science

Bootstrap Methods: correct estimate prediction error

Note:

- each bootstrap sample has N observations;
- some of the original observations are included more than once;
- some of them (in average, 0.368N) are not included at all;
 - these are not used to compute the predictions;
 - they can be used as a test set,

$$\widehat{\mathsf{Err}}^{(1)} = \frac{1}{N} \sum_{i=1}^{N} \frac{1}{|C_{[-i]}|} \sum_{b \in C_{[-i]}} L(y_i, \hat{f}_b^*(x_i))$$

where $C_{[-i]}$ is the set of indeces of the bootstrap samples which do not contain the observation i and $|C_{[-i]}|$ denotes its cardinality.

STK-IN4300: lecture 3 15/42 STK-IN4300: lecture 3 16/42

Bootstrap Methods: 0.632 bootstrap

Issue:

- the average number of unique observations in the bootstrap sample is $0.632N \rightarrow$ not so far from 0.5N of 2-fold CV;
- similar bias issues of 2-fold CV;
- ullet $\widehat{\mathsf{Err}}^{(1)}$ slightly overestimates the prediction error.

To solve this, the 0.632 bootstrap estimator has been developed,

$$\widehat{\mathsf{Err}}^{(0.632)} = 0.368 \; \overline{\mathsf{err}} + 0.632 \; \widehat{\mathsf{Err}}^{(1)}$$

- in practice it works well;
- in case of strong overfit, it can break down;
 - consider again the previous classification problem example;
 - with 1-nearest neighbour, $\overline{\text{err}} = 0$;
 - $\widehat{\mathsf{Err}}^{(0.632)} = 0.632 \ \widehat{\mathsf{Err}}^{(1)} = 0.632 \times 0.5 = 0.316 \neq 0.5.$

STK-IN4300: lecture 3 17/ 42

STK-IN4300 - Statistical Learning Methods in Data Science

Bootstrap Methods: 0.632+ bootstrap

The quantity $\hat{\gamma}$ is used to estimate the relative overfitting rate,

$$\hat{R} = \frac{\widehat{\mathsf{Err}}^{(1)} - \overline{\mathsf{err}}}{\hat{\gamma} - \overline{\mathsf{err}}},$$

which is then use in the 0.632+ bootstrap estimator,

$$\widehat{\mathsf{Err}}^{(0.632+)} = (1 - \hat{w}) \; \overline{\mathsf{err}} + \hat{w} \; \widehat{\mathsf{Err}}^{(1)},$$

where

$$\hat{w} = \frac{0.632}{1 - 0.368 \, \hat{R}}.$$

Bootstrap Methods: 0.632+ bootstrap

Further improvement, 0.632+ bootstrap:

- based on the no-information error rate γ;
- γ takes into account the amount of overfitting;
- γ is the error rate if predictors and response were independent;
- computed by considering all combinations of x_i and y_i ,

$$\hat{\gamma} = \frac{1}{N} \sum_{i=1}^{N} \frac{1}{N} \sum_{i'=1}^{N} L(y_i, \hat{f}(x_{i'})).$$

STK-IN4300: lecture 3 18/42

STK-IN4300 - Statistical Learning Methods in Data Science

Methods using Derived Input Directions: summary

- Principal Components Regression
- Partial Least Squares

STK-IN4300: lecture 3 19/42 STK-IN4300: lecture 3 20/42

Principal Component Regression: singular value decomposition

Consider the singular value decomposition (SVD) of the $N \times p$ (standardized) input matrix X,

$$X = UDV^T$$

where:

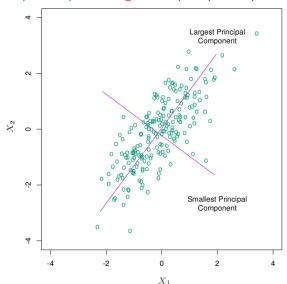

- U is the $N \times p$ orthogonal matrix whose columns span the column space of X;
- D is a $p \times p$ diagonal matrix, whose diagonal entries $d_1 \geqslant d_2 \geqslant \cdots \geqslant d_p \geqslant 0$ are the singular values of X;
- V is the $p \times p$ orthogonal matrix whose columns span the row space of X.

STK-IN4300: lecture 3 21/ 42

STK-IN4300 - Statistical Learning Methods in Data Science

Principal Component Regression: principal components

Principal Component Regression: principal components

Simple algebra leads to

$$X^TX = VD^2V^T$$

the eigen decomposition of X^TX (and, up to a constant N, of the sample covariance matrix $S = X^TX/N$).

Using the eigenvectors v_j (columns of V), we can define the principal components of X,

$$z_j = Xv_j.$$

 the first principal component z₁ has the largest sample variance (among all linear combinations of the columns of X);

$$\mathsf{Var}(z_1) = \mathsf{Var}(Xv_1) = \frac{d_1^2}{N}$$

• since $d_1 \ge \cdots \ge d_p \ge 0$, then $Var(z_1) \ge \cdots \ge Var(z_p)$.

STK-IN4300: lecture 3 22/ 42

STK-IN4300 - Statistical Learning Methods in Data Science

Principal Component Regression: principal components

Principal component regression (PCR):

- use $M \leq p$ principal components as input;
- regress y on z_1, \ldots, z_M ;
- since the principal components are orthogonal,

$$\hat{y}_{\mathsf{pcr}}(M) = \bar{y} + \sum_{m=1}^{M} \hat{\theta}_{m} z_{m},$$

where $\hat{\theta}_m = \langle z_m, y \rangle / \langle z_m, z_m \rangle$.

Since z_m are linear combinations of x_j ,

$$\hat{eta}_{\mathsf{pcr}}(M) = \sum_{m=1}^M \hat{ heta}_m v_m.$$

STK-IN4300: lecture 3 23/42 STK-IN4300: lecture 3 24/42

Principal Component Regression: remarks

Note that:

- PCR can be used in high-dimensions, as long as M < n;
- idea: remove the directions with less information:
- if M = N, $\hat{\beta}_{pcr}(M) = \hat{\beta}_{OLS}$;
- M is a tuning parameter, may be chosen via cross-validation;
- shrinkage effect (clearer later);
- principal component are scale dependent, it is important to standardize X!

STK-IN4300: lecture 3 25/42

UiO: University of Oslo

STK-IN4300 - Statistical Learning Methods in Data Science

Partial Least Squares: algorithm

- 1. standardize each x_i , set $\hat{y}^{[0]} = \bar{y}$ and $x_i^{[0]} = x_i$;
- 2. For m = 1, 2, ..., p,
 - (a) $z_m = \sum_{j=1}^p \hat{\varphi}_{mj} x_j^{[m-1]}$, with $\hat{\varphi}_{mj} = \langle x_i^{[m-1]}, y \rangle$;

 - $\begin{array}{ll} \text{(b)} & \hat{\theta}_m = \langle z_m, y \rangle / \langle z_m, z_m \rangle; \\ \text{(c)} & \hat{y}^{[m]} = \hat{y}^{[m-1]} + \hat{\theta} z_m; \\ \text{(d)} & \text{orthogonalize each } x_j^{[m-1]} & \text{with respect to } z_m, \end{array}$

$$x_j^{[m]} = x_j^{[m-1]} - \left(\frac{\langle z_m, x_j^{[m-1]} \rangle}{\langle z_m, z_m \rangle}\right) z_m, \quad j = 1, \dots, p;$$

3. output the sequence of fitted vectors $\{\hat{y}^{[m]}\}_{1}^{p}$.

Partial Least Squares: idea

Partial least square (PLS) is based on an idea similar to PCR:

- construct a set of linear combinations of X;
- PCR only uses X, ignoring y;
- in PLS we want to also consider the information on y;
- as for PCR, it is important to first standardize X.

STK-IN4300: lecture 3 26/42

STK-IN4300 - Statistical Learning Methods in Data Science

Partial Least Squares: step by step

First step:

- (a) compute the first PLS direction, $z_1 = \sum_{i=1}^p \hat{\varphi}_{1i} x_i$,
 - based on the relation between each x_i and y, $\hat{\varphi}_1 = \langle x_i, y \rangle$;
- (b) estimate the related regression coefficient, $\hat{\theta}_1 = \frac{\langle z_1, y \rangle}{\langle z_1, z_1 \rangle} = \frac{\overline{z_1} y}{z_1^2}$;
- (c) model after the first iteration: $\hat{y}^{[1]} = \bar{y} + \hat{\theta}_1 z_1$:
- (d) orthogonalize x_1, \ldots, x_p w.r.t. z_1 , $x_j^{[2]} = x_j \left(\frac{\langle z_1, x_j \rangle}{\langle z_1, z_1 \rangle}\right) z_1$;

We are now ready for the second step . . .

STK-IN4300: lecture 3 27/42 STK-IN4300: lecture 3 28/42 ... using $x_j^{[2]}$ instead of x_j :

- (a) compute the second PLS direction, $z_2 = \sum_{j=1}^p \hat{\varphi}_{2j} x_j^{[2]}$,
 - based on the relation between each $x_j^{[2]}$ and $y,\ \hat{\varphi}_2=\langle x_j^{[2]},y \rangle;$
- (b) estimate the related regression coefficient, $\hat{\theta}_2 = \frac{\langle z_2, y \rangle}{\langle z_2, z_2 \rangle}$;
- (c) model after the second iteration: $\hat{y}^{[2]} = \bar{y} + \hat{\theta}_1 z_1 + \hat{\theta}_2 z_2$;
- (d) orthogonalize $x_1^{[2]},\ldots,x_p^{[2]}$ w.r.t. z_2 , $x_j^{[2]}=x_j^{[2]}-\left(\frac{\langle z_2,x_j^{[2]}\rangle}{\langle z_2,z_2\rangle}\right)z_2$;

and so on, until the $M \leq p$ step $\rightarrow M$ derived inputs.

STK-IN4300: lecture 3 29/ 42

UiO : University of Oslo

STK-IN4300 - Statistical Learning Methods in Data Science

Ridge Regression: historical notes

When two predictors are strongly correlated → collinearity;

- in the extreme case of linear dependency → super-collinearity;
- in the case of super-collinearity, X^TX is not invertible (not full rank);

Hoerl & Kennard (1970): $X^TX \to X^TX + \lambda I_p$, where $\lambda > 0$ and

$$I_p = \left(\begin{array}{cccc} 1 & 0 & \dots & 0 \\ 0 & 1 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & 1 \end{array} \right).$$

With $\lambda > 0$, $(X^TX + \lambda I_p)^{-1}$ exists.

Partial Least Squares: PLS versus PCR

Differences:

PCR the derived input directions are the principal components of X, constructed by looking at the variability of X;

PLS the input directions take into consideration both the variability of X and the correlation between X and y.

Mathematically:

PCR $\max_{\alpha} Var(X\alpha)$, s.t.

$$|\alpha| = 1 \text{ and } \alpha^T S v_\ell = 0, \ \ell = 1, \dots, M-1;$$

 $\mathsf{PLS}\ \mathsf{max}_{\alpha}\mathsf{Cor}^2(y,X\alpha)\mathsf{Var}(X\alpha)\text{, s.t.}$

$$|\alpha| = 1 \text{ and } \alpha^T S \varphi_\ell = 0, \ \forall \ell < M.$$

In practice, the variance tends to dominate → similar results!

STK-IN4300: lecture 3 30 / 42

STK-IN4300 - Statistical Learning Methods in Data Science

Ridge Regression: estimator

Substituting X^TX with $X^TX + \lambda I_p$ in the LS estimator,

$$\hat{\beta}_{\mathsf{ridge}}(\lambda) = (X^T X + \lambda I_p)^{-1} X^T y.$$

Alternatively, the ridge estimator can be seen as the minimizer of

$$\sum_{i=1}^{N} (y_i - \beta_0 - \sum_{i=1}^{p} \beta_j x_{ij})^2,$$

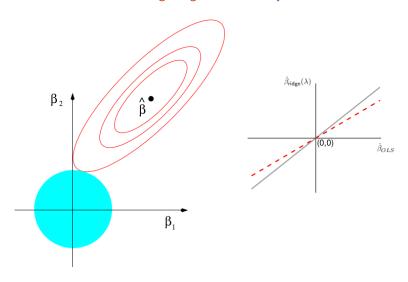

subject to $\sum_{j=1}^{p} \beta_j^2 \leqslant t$.

Which is the same as

$$\hat{\beta}_{\mathsf{ridge}}(\lambda) = \mathsf{argmin}_{\beta} \left\{ \sum_{i=1}^{N} (y_i - \beta_0 - \sum_{j=1}^{p} \beta_j x_{ij})^2 + \lambda \sum_{j=1}^{p} \beta_j^2 \right\}.$$

STK-IN4300: lecture 3 31/42 STK-IN4300: lecture 3 32/42

Ridge Regression: visually

STK-IN4300: lecture 3 33/42

STK-IN4300 - Statistical Learning Methods in Data Science

Ridge Regression: remarks

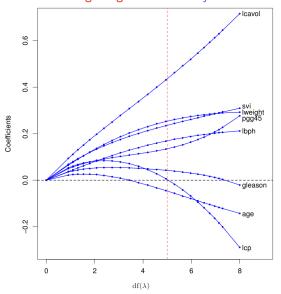

Note:

- ridge solution is not equivariant under scaling $\rightarrow X$ must be standardized before applying the minimizer;
- the intercept is not involved in the penalization;
- Bayesian interpretation:
 - $Y_i \sim N(\beta_0 + x_i^T \beta, \sigma^2);$ $\beta \sim N(0, \tau^2);$ $\lambda = \sigma^2 / \tau^2;$

 - $\hat{\beta}_{ridge}(\lambda)$ as the posterior mean.

Ridge Regression: visually

STK-IN4300: lecture 3 34/42

STK-IN4300 - Statistical Learning Methods in Data Science

Ridge Regression: bias

$$\begin{split} E[\hat{\beta}_{\mathsf{ridge}}(\lambda)] &= E[(X^TX + \lambda I_p)^{-1}X^Ty] \\ &= E[(I_p + \lambda (X^TX)^{-1})^{-1}\underbrace{(X^TX)^{-1}X^Ty}_{\hat{\beta}_{\mathsf{LS}}}] \\ &= \underbrace{(I_p + \lambda (X^TX)^{-1})^{-1}}_{w_{\lambda}} E[\hat{\beta}_{\mathsf{LS}}] \\ &= w_{\lambda}\beta \implies E[\hat{\beta}_{\mathsf{ridge}}(\lambda)] \neq \beta \text{ for } \lambda > 0. \end{split}$$

- $\lambda \to 0$, $E[\hat{\beta}_{ridge}(\lambda)] \to \beta$;
- $\lambda \to \infty$, $E[\hat{\beta}_{\mathsf{ridge}}(\lambda)] \to 0$ (without intercept);
- due to correlation, $\lambda_a > \lambda_b \Rightarrow |\hat{\beta}_{\mathsf{ridge}}(\lambda)| > |\hat{\beta}_{\mathsf{ridge}}(\lambda)|$

STK-IN4300: lecture 3 35/42 STK-IN4300: lecture 3 36/42 Consider the variance of the ridge estimator,

$$\begin{split} \mathsf{Var}[\hat{\beta}_{\mathsf{ridge}}(\lambda)] &= \mathsf{Var}[w_{\lambda}\hat{\beta}_{\mathsf{LS}}] \\ &= w_{\lambda} \mathsf{Var}[\hat{\beta}_{\mathsf{LS}}] w_{\lambda}^T \\ &= \sigma^2 w_{\lambda} (X^T X)^{-1} w_{\lambda}^T. \end{split}$$

Then.

$$\begin{split} & \operatorname{Var}[\hat{\beta}_{\mathsf{LS}}] - \operatorname{Var}[\hat{\beta}_{\mathsf{ridge}}(\lambda)] = \sigma^2 \left[(X^T X)^{-1} - w_{\lambda} (X^T X)^{-1} w_{\lambda}^T \right] \\ &= \sigma^2 w_{\lambda} \left[(I_p + \lambda (X^T X)^{-1}) (X^T X)^{-1} (I_p + \lambda (X^T X)^{-1})^T - (X^T X)^{-1} \right] w_{\lambda}^T \\ &= \sigma^2 w_{\lambda} \left[((X^T X)^{-1} + 2\lambda (X^T X)^{-2} + \lambda^2 (X^T X)^{-3}) - (X^T X)^{-1} \right] w_{\lambda}^T \\ &= \sigma^2 w_{\lambda} \left[2\lambda (X^T X)^{-2} + \lambda^2 (X^T X)^{-3}) \right] w_{\lambda}^T > 0 \\ & \text{(since all terms are quadratic and therefore positive)} \end{split}$$

$$\implies \mathsf{Var}[\hat{\beta}_{\mathsf{ridge}}(\lambda)] \leq \mathsf{Var}[\hat{\beta}_{\mathsf{LS}}]$$

STK-IN4300: lecture 3 37/42

STK-IN4300 - Statistical Learning Methods in Data Science

Ridge Regression: more about shrinkage

Recall the SVD decomposition $X = UDV^T$, and the properties

$$U^T U = I_p = V^T V.$$

$$\begin{split} \hat{\beta}_{\mathsf{LS}} &= (X^T X)^{-1} X^T y & \hat{y}_{\mathsf{LS}} &= X \hat{\beta}_{\mathsf{LS}} \\ &= (V D U^T U D V^T)^{-1} V D U^T y & = U D V^T V D^{-2} D U^T y \\ &= (V D^2 V^T)^{-1} V D U^T y & = U D D^{-2} D U^T y \\ &= V D^{-2} V^T V D U^T y & = U U^T y \\ &= V D^{-2} D U^T y \end{split}$$

Ridge Regression: degrees of freedom

Note that the ridge solution is a linear combination of y, as the least squares one:

•
$$\hat{y}_{\text{LS}} = \underbrace{X(X^TX)^{-1}X^T}_{H} y \longrightarrow df = \text{trace}(H) = p;$$

•
$$\hat{y}_{\mathsf{ridge}} = \underbrace{X(X^TX + \lambda I_p)^{-1}X^T}_{H_{\lambda}} y \longrightarrow df(\lambda) = \mathsf{trace}(H_{\lambda});$$

- trace $(H_{\lambda}) = \sum_{i=1}^{p} \frac{d_{j}^{2}}{d_{s}^{2} + \lambda}$;
- d_i is the diagonal element of D in the SVD of X;
- $\lambda \to 0$, $df(\lambda) \to p$;
- $\lambda \to \infty$, $df(\lambda) \to 0$.

STK-IN4300: lecture 3 38 / 42

STK-IN4300 - Statistical Learning Methods in Data Science

Ridge Regression: more about shrinkage

$$\begin{split} \hat{\beta}_{\mathsf{ridge}} &= (X^TX + \lambda I_p)^{-1}X^Ty & \hat{y}_{\mathsf{ridge}} = X\hat{\beta}_{\mathsf{ridge}} \\ &= (VDU^TUDV^T + \lambda I_p)^{-1}VDU^Ty & = UDV^TV(D^2 + \lambda I_p)^{-1}U^Ty \\ &= (VD^2V^T + \lambda VV^T)^{-1}VDU^Ty & = UV^TVD^2(D^2 + \lambda I_p)^{-1}U^Ty \\ &= V(D^2 + \lambda I_p)^{-1}V^TVDU^Ty & = UD^2(D^2 + \lambda I_p)^{-1}U^Ty \\ &= V(D^2 + \lambda I_p)^{-1}U^Ty & & \downarrow \\ &\sum_{j=1}^p \frac{d_j^2}{d_j^2 + \lambda} \end{split}$$

So:

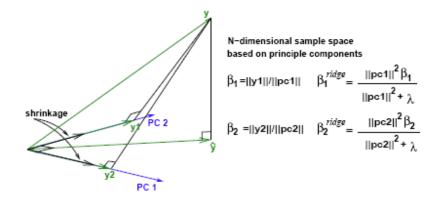

- small singular values d_j correspond to directions of the column space of X with low variance;
- ridge regression penalizes the most these directions.
